

Explanation of Joi Validation Code

What is JOI.

Joi is a powerful schema description language and data validator for JavaScript. It allows you to define the structure and rules for your data, making it easy to validate incoming requests in web applications.

```
let { error, value } = schema.validate(req.body, {
  abortEarly: false,
});
```

This code uses **Joi** (or a similar validation library) to validate incoming request data.

Breakdown

`schema`

This is your Joi schema. It defines what shape and rules `req.body` must follow.

`schema.validate(req.body, ...)`

You are checking if `req.body` matches the schema rules.

`{ abortEarly: false }`

By default, Joi stops at the first error.

This option tells it:

👉 Collect *all* validation errors, not just the first one.

`{ error, value } = ...`

This is **destructuring** the result:

- `error` → contains validation errors (if any)
- `value` → contains the cleaned/validated data

In Simple Words

This line validates the request body and gives you:

- All validation errors (if something is wrong)
- A safe, validated version of the data to use in your app
